

Simulation-Driven Design of Sailing Yachts and Motor Boats

VII International Conference on
Computational Methods in Marine Engineering
MARINE 2017
Nantes, France 15-17 May 2017

Dr.-Ing. Bodo Hasubek, www.dreamcatcherone.de

Overview

- Motivation
- Designs and Design objectives
- Parametric models
- Interfacing with CFD codes
- Optimization strategies
- Results

Motivation

- Yacht design is traditionally based on previous designs and systematic hull series (e.g. Delft series)
- The data base for catamaran designs and planing hulls is rather limited
- Model tests are prohibitively expensive
- The Simulation-Driven-Design approach allows to relate small design changes to performance

The Designs

DreamCatcherOne

- New Design
- Sailing catamaran (LWL ~20m)
- 36t displacement
- Displacement speeds
- Two speed optimization
($F_n = 0.3$ (8.2kts) and $F_n = 0.44$ (12kts))
- Different CFD codes used
(SHIPFLOW[®], FINE[™]/Marine)
- > 4500 models investigated
- **Design objective:**
Good light wind performance

Riva Junior

- Classical Design
- Motor boat (LWL ~5.66m)
- 1.3t displacement
- Planing speed
- One speed optimization
($F_n = 1.32$ (18kts))
- One CFD codes used
(FINE[™]/Marine)
- ~ 100 models investigated
- **Design objective:**
Min. resistance at design speed

Parametric model in Yacht Design

- Key success factors
 - Reduce the number of independent parameters
 - Parameters should influence known performance aspects as directly as possible
 - Large parameter ranges to cover “unusual” designs
 - Provide suitable constraints
- CAESES[®] parametric CAD system
 - define complex geometric shapes based on mathematical models
 - integrates well with a many CFD solvers such as SHIPFLOW[®], FINE[™]/Marine, STAR-CCM+ or OpenFOAM

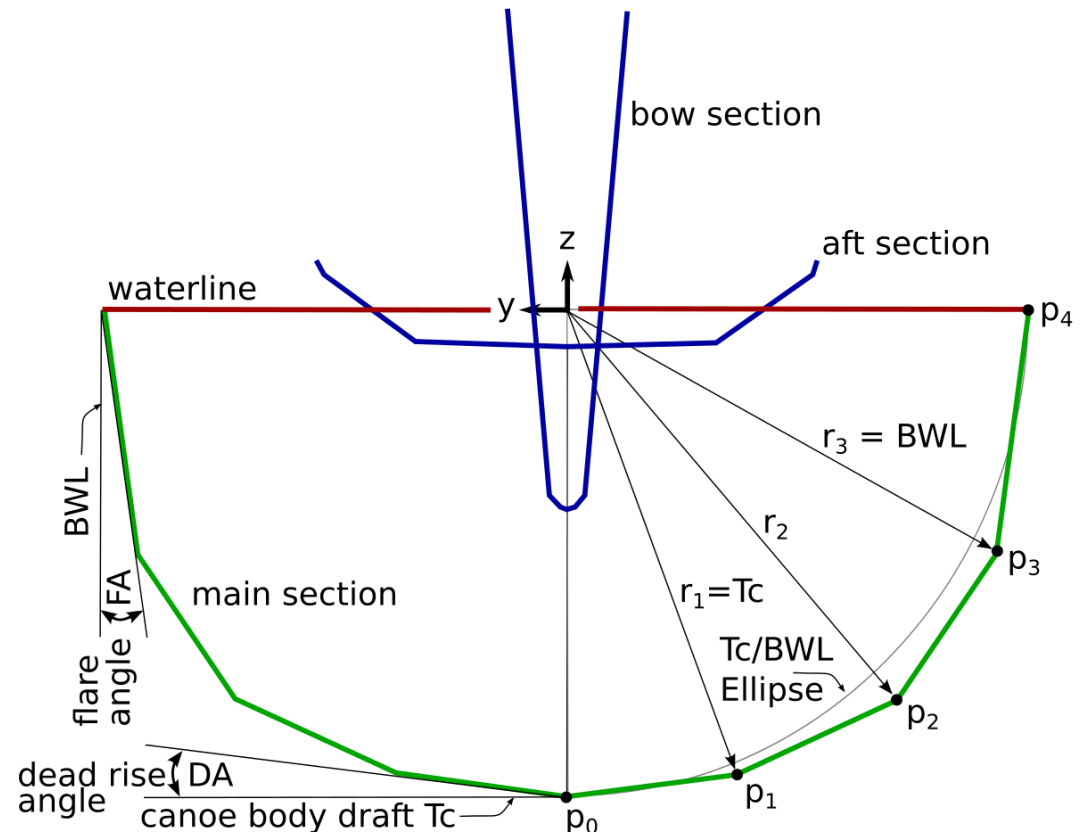

DCOne: Three-/Four plate models

- All parametric hull designs used here use a section engine
- Shape parameters
 - waterline curve, center line curve, dead rise angle curve and flare angle curve, sectional area, longitudinal position
- Dependent parameters
 - side angle is derived using a quadratic equation minimizing the length $p_1p_2p_3p_4$
 - displacement by variation of sectional area

DCOne: Three-/Four plate models

- All parametric hull designs used here use a section engine
- Shape parameters
 - waterline curve, center line curve, dead rise angle curve and flare angle curve, sectional area, longitudinal position
- Dependent parameters
 - side angle is derived using a quadratic equation minimizing the length $p_1p_2p_3p_4$
 - displacement by variation of sectional area

DCOne: Modeling Pitfall

Choosing parameters that directly influence performance does not always work:

- Sectional area curve is translated into a multitude of hard chined sections
- The curves connecting the corner points are not fair but show wave-like shapes
- Too many constraints

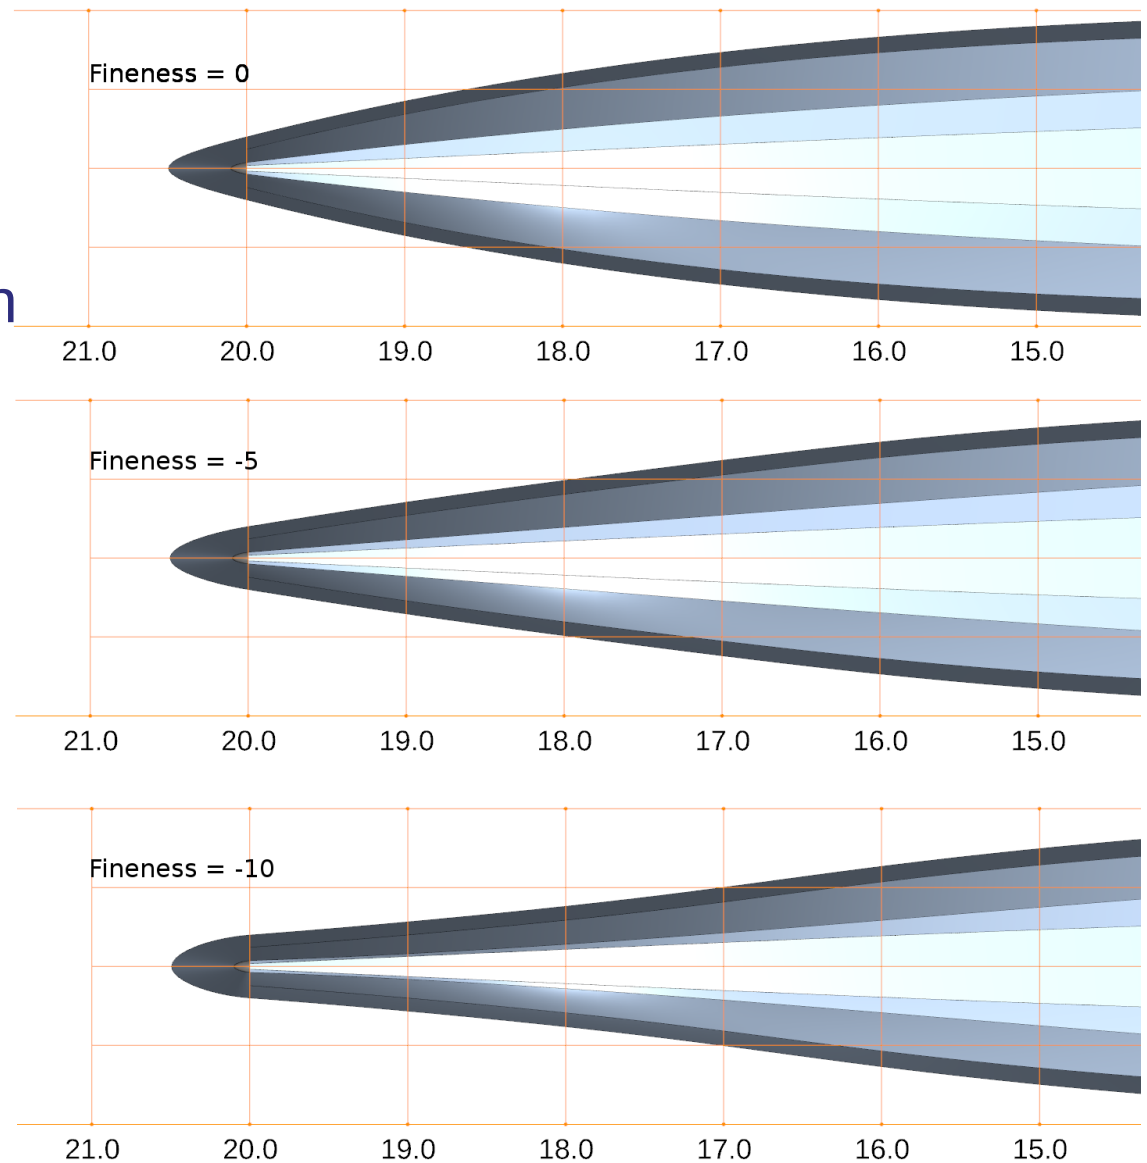

DCOne: Fair chines

- Three section only: stern, main, bow
- The chines depend on the section points which are connected by C2-continuous splines
- The chine-curves are used as rail curves for developable surfaces

DCOne: Design parameters

- Maximum Beam
- Beam at stern
- Bow Fineness
- Rocker angle at the stern
- Draft at stern
- Area of stern section
- Flare angle at stern
- Beam-to-Draft ratio
- Dead rise angle curve
- Flare angle curve
- Draft at bow
- Longitudinal position of the main section
- ...

Riva: Parametric model

- Different approach:
 - Define hard chines first, then sections
- Chines are defined by generic curves in 3D that are based on two planar curves in the XY and XZ planes
- Skinning by a mix of ruled surfaces and metasurfaces

Riva: Parametric model

- Hull is composed of different parts that seamlessly connect at the chines
- Each part can be separately varied based on separate parameter curves
- In longitudinal direction the sections are varied based on a mathematical model of the section (i.e a program written within the CAD environment (CAESES[®]) to generate the meta surfaces

Riva: Design Parameters

- Beam
- Hollowness
- Rocker
- Deadrise

See:

webapps.caeses.com

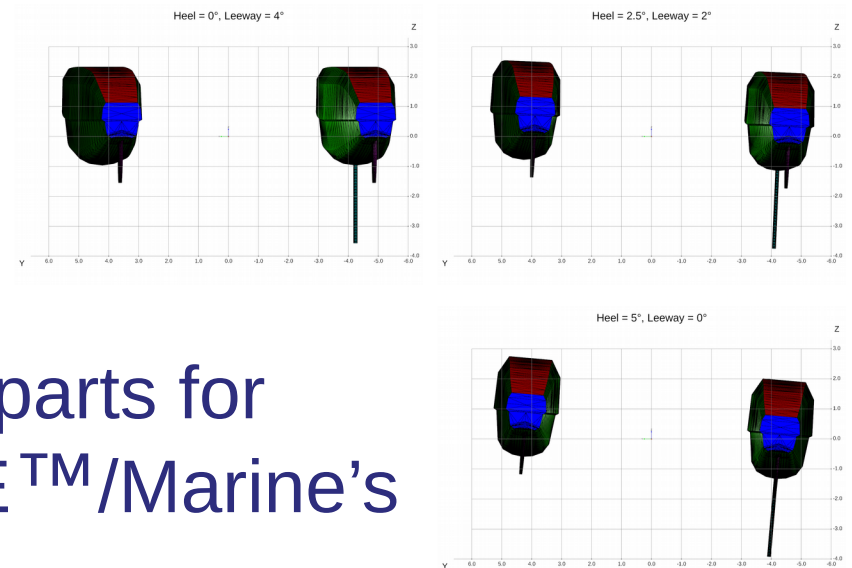

DCOne: CFD Model setup 1

- Parametric model in CAESES®
 - Hull geometry
 - Fixed displacement
- Interface to SHIPFLOW®
 - Section created in CAESES®
 - Section resolution adjusted for best meshing results

DCOne: CFD Model setup 2

- Parametric model in CAESES
 - Heel / Leeway transformations
 - Fixed displacement
 - Variable rudder angles and daggerboard sweep angles
- Interface to FINE™/Marine
 - Triangulation in CAESES®
 - Water-tight STL body
 - STL-triangulation exported (multibody STL)
- Different colours for different parts for automatic recognition in FINE™/Marine's "C-Wizard"

Riva: CFD Model setup

- Triangulation of hull and simulation domain
- Colored STL Export as in DCOne Case 2

Optimization strategies

DreamCatcherOne

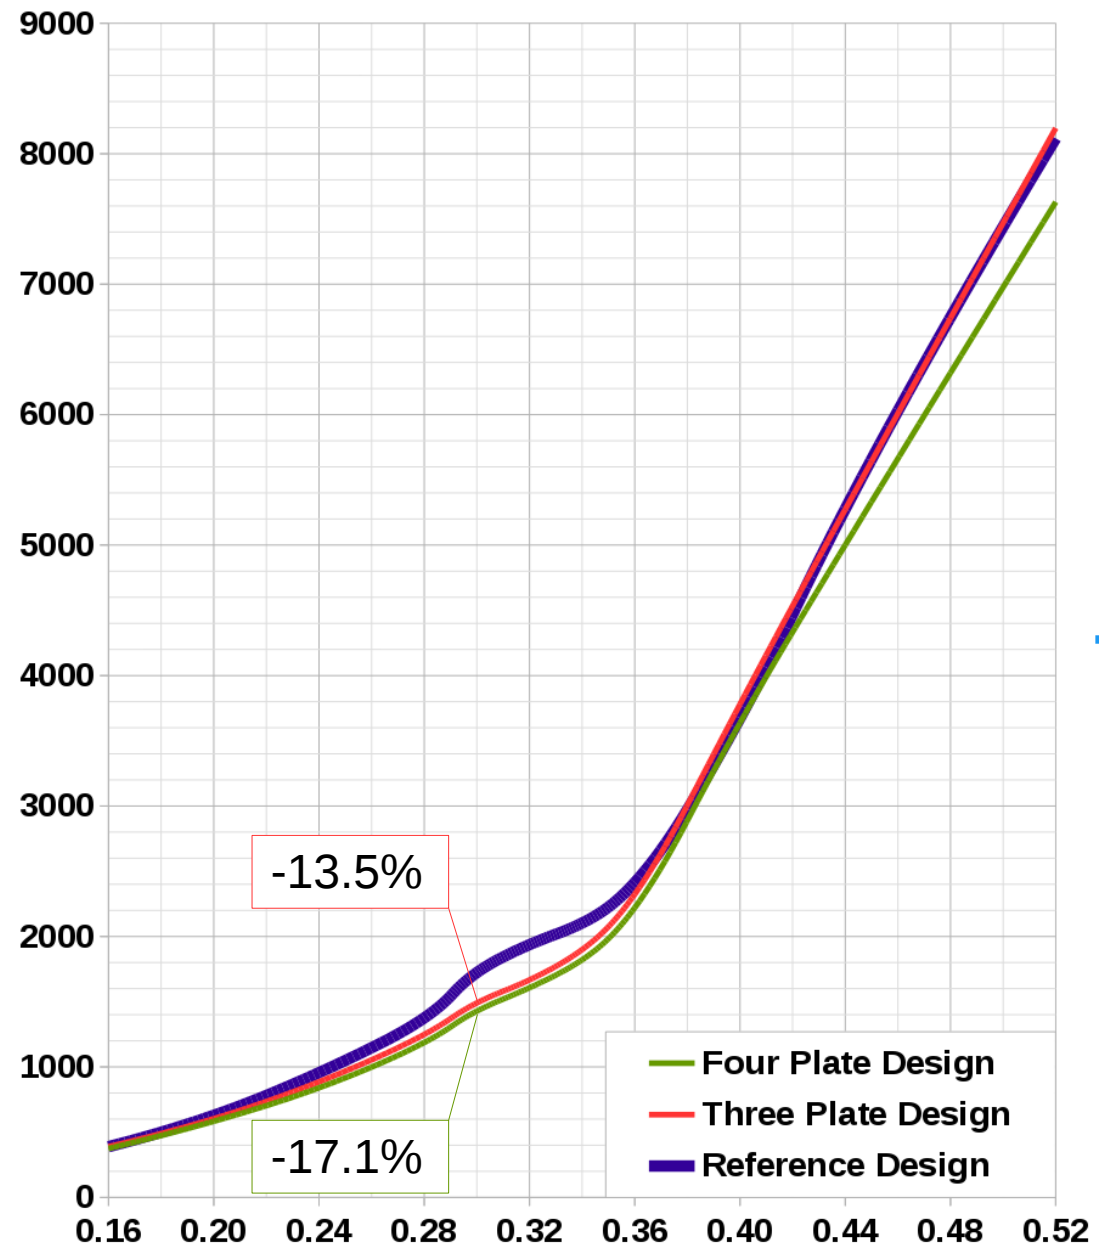

- Wave resistance single hull
 - “Design of Experiments”
 - ~4000 models, 8000 calculations
- Total resistance, zonal approach
 - ~500 models, 1000 calculations
 - Selection criterium: Weighted sum of resistances at $F_n = 0.3$ and $F_n = 0.44$
- Total resistance appended catamaran model (RANSE solver)
 - ~200 simulations
 - Verification of best single hull designs, hull distance, ...

Riva Junior

- Total resistance (RANSE solver)
 - “Designs of Experiments”
 - Evaluation of the design space
 - ~100 models
 - Selection criterium: Lowest resistance at design speed
- Tsearch
 - automatic using deterministic gradient-free search strategy to find the best model in a limited design space

DCOne: Numerical Results 1

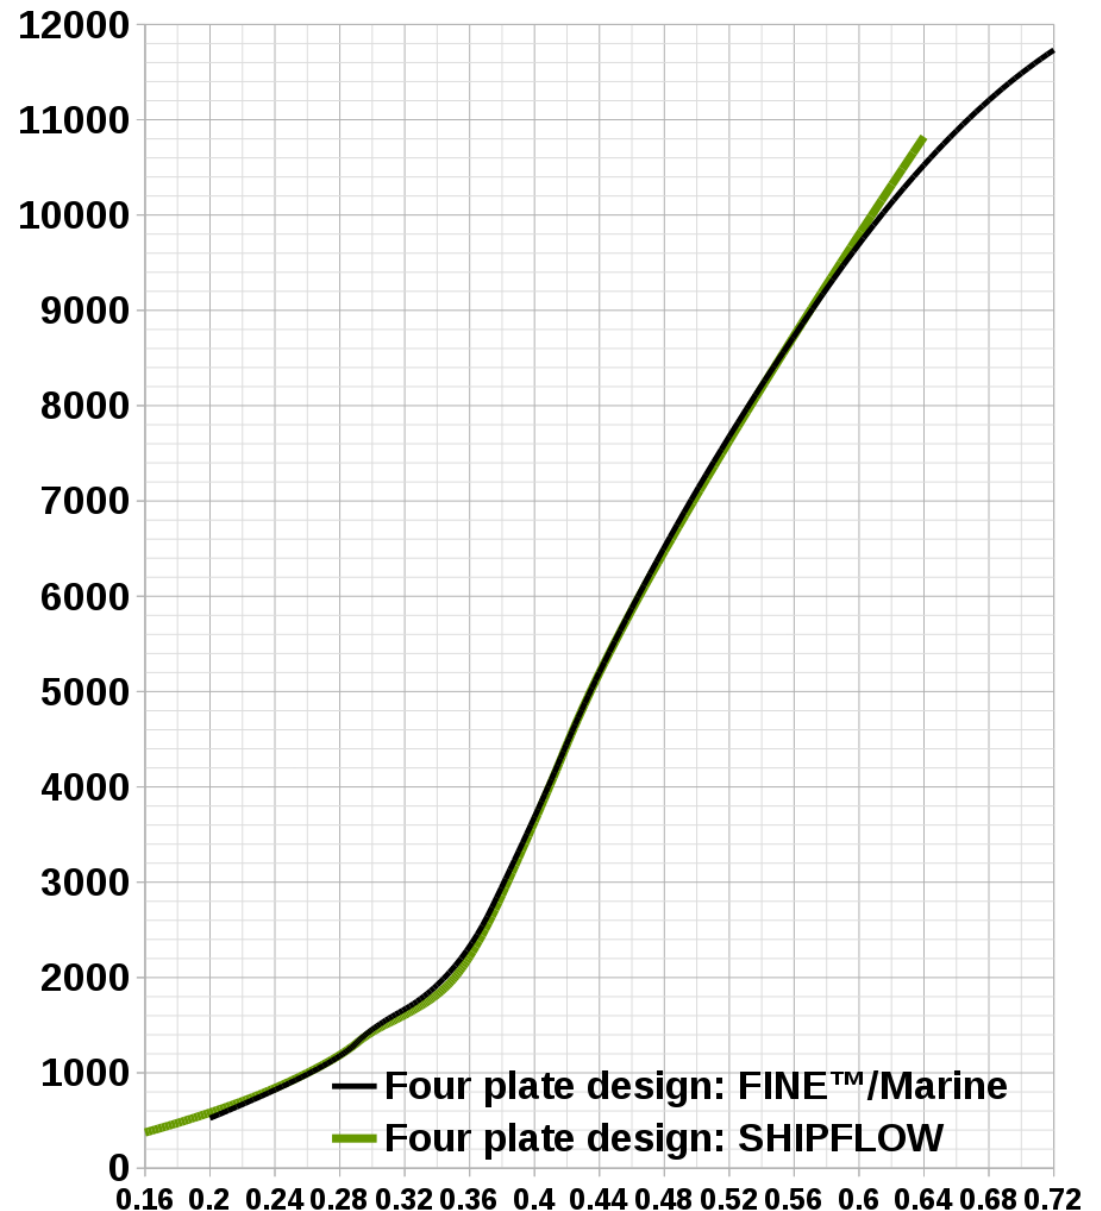

- Best three and four plate designs
- Complete speed range
- Significant improvement between $F_n=0.28$ and 0.36 (7.5 and 9.5 kts) (Hull speed 10.9kts)
- Four plate design better at higher velocities

DCOne: Numerical Results 2

- Result verification using RANSE solver (FINE™/Marine)
- Maximum deviation at the optimization points
 $F_n=0.30$ 1.8%
 $F_n=0.44$ 0.1%
- Maximum deviation at other calculation points
 $F_n=0.36$ 5.5%

➔ Reliable results

DCOne: Visual inspection 1

Pressure distribution: rectangular shape vs. elliptical appendage shapes

DCOne: Visual inspection 2

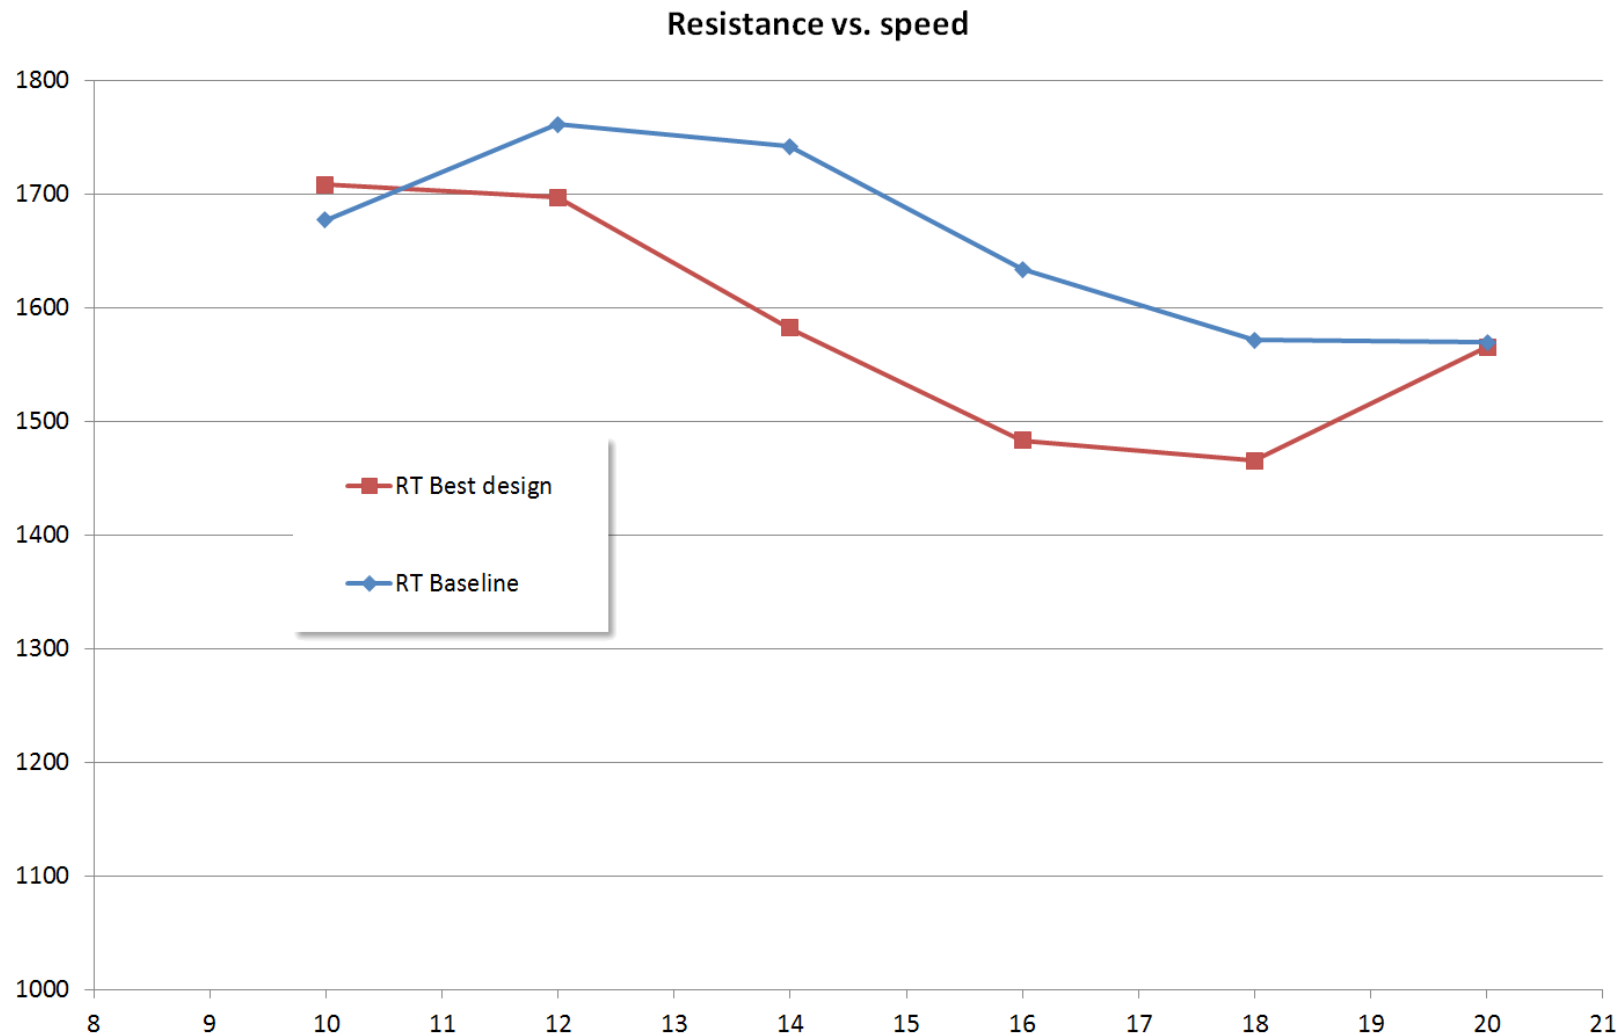

Wave elevation: Bottom view, no rudder ventilation

Riva: Numerical Results 1

Typical result of a one point optimization

Riva: Numerical Results 2

Resistance: 7% reduction at design speed

Riva: Visual inspection 1

Base line at design speed (18kts)

Riva: Visual inspection 2

Best Design at design speed (18 kts)

Conclusions

- Key success factors
 - Selection of design objectives
 - Fully parametric models
 - Automation of CFD simulations
 - Flexible optimization strategies
- Simulation Driven Design is a versatile tool to solve complex yacht design problems from overall design aspects to specific details

Dreamcatcher One - Ein Katamaran-Eigenbau aus Aluminium

Dreamcatcher One - Entwurf 2016

So lange ich denken kann, habe ich immer davon geträumt, ein Segelkatamaran zu bauen. Nun also dieses Projekt. Der Katamaran soll aus Aluminium entstehen, weil dies das geeignetste Material für ein One-Off-Selbstbau darstellt. Der Selbstbau hat viele Vorteile, wenn man von Anfang an beginnt: Am Ende kenne ich jede Schraube auf dem Schiff, was gerade für Reisen in abgelegene Gebiete von entscheidender Bedeutung sein kann. Der Nachteil ist, dass man leicht das Ziel aus den Augen verlieren kann und im schlimmsten Fall nie fertig wird.

Eigenes Design

Die zugegebenermaßen üppigen Abmessung von etwa 20 Metern LOA waren eigentlich nicht mein ursprünglicher Wunsch, aber Komfort- und Sicherheitsanforderungen bei gleichzeitiger Segelperformance lassen sich nicht in einem kürzeren Design vereinbaren. Schon in der Designphase soll immer auf einfache Baubarkeit geachtet werden, so dass für einen Selbstbauer nur ein Knickspanter in Frage kommt.

Projektplan
